PRELIMINARY WATER & SEWER REPORT FOR TY JENKINS HANGAR 16061 N. 81ST STREET SCOTTSDALE, ARIZONA 85260

#### PREPARED FOR:

Larson Associates Architects 3807 N. 24<sup>th</sup> Street Suite 100 Phoenix, Arizona 85016

Job Number 24-013 September 17 2024 Rev January 7, 2025

#### INTRODUCTION

In accordance with Arizona Administrative Code R18-4-505.B and R18-9-E301.C, the following preliminary water & sewer report is being provided in conjunction with the Ty Jenkins Hanger project.

The project is located at 16061 N. 81st Street in Scottsdale, Arizona. The parcel is Lot 34 of North Scottsdale Airpark Unit 1 as recorded in Book 327 of Records, Page 12 at the Maricopa County Recorder's Office.

#### **DESIGN CRITERIA**

An existing 12" water line is located in 81st Street. The intent is to tap this existing water main to serve the buildings fire and domestic demand. An existing public fire hydrant is located near the northwest property corner. This hydrant will provide the required fire coverage for the project.

An 8" sewer main is also located within the 81st Street right of way. This main will be tapped to provide sewer service for the new building.

#### **DEMANDS**

#### WATER

The estimated average day water demand for this property is established by Figure 6.1-2 in the City of Scottsdale DSPM. Office Land Use was used to determine the flow from the office area of the building. The Ty Jenkins Hangar has a total office floor area of 4,961 square feet. The hangar portion of the building will be provided with a hose bib for washing the hangar floor. It is estimated that the floor will be washed once per week and will use approximately 200 gallons per washing operation with a peak flow of 10 gallons per minute.

The water use computations are summarized in the table below.

	GPD/SF	GPD	GPM/SF	GPM
Inside Use	0.5	4,544	.000695	6.3
Outside Use	0.1	496	.000139	0.7
Total Use	0.6	5,040	.000834	7.0

The maximum day flow peaking factor is 2.0 giving a maximum day flow of 10,080 gallons per day and 14.0 gallons per minute. The peak hour flow is 3.5 times the average day flow giving a peak hour flow of 10,420 gallons per day and 14.3 gallons per minute. Adding the floor washing operation to the peak hour gives a flow of 17,640 gallons per day and 24.5 gallons per minute.

The fire flow requirement was determined using the International Fire Code Appendix B. The total fire flow area of the building is 17,081 square feet with a V-B construction type. Per table B105.1 the required fire flow is 3,500 gpm. The code allows a 50% reduction for buildings that are equipped with automatic fire sprinkler systems. The required fire flow after the reduction is 1,750 gpm.

#### **SEWER**

The average daily sewer flow is established by Figure 7.1-2 in the DSPM. For an office land use, the average daily sewage flow is estimated to be 0.4 gallons per square foot with a peaking factor of 3.0. Using the Ty Jenkins Hangar office area, the average daily sewage flow computes to 1,984 gallons per day with ae peak flow of 5,952 gallons per day. Adding the floor washing operation to the peak office flow yields a total wastewater flow of 6,152 gallons per day. Assuming that the sewer flow occurs over a 12 hour period, the peak sewer discharge from the project is 8.54 gallons per minute.

#### **EXISTING WATER FACILITIES**

An existing 12" PVC water line is located in 81st Street. A flow test was performed on this waterline on September 16<sup>th</sup>, 2024. The results are listed in the table below:

	RawTestData	Data with 10% Safety Factor		
Static Pressure (psi)	67.0	60.3		
Residual Pressure (psi)	51.0	44.3		
Flow (gpm)	1,783	1,783		
Flow at 20 psi (gpm)	3,191	2,937		

See Appendix for the flow test results.

#### **PROPOSED WATER FACILITIES**

A new 1" water meter is proposed to serve the new building's domestic demand. A new 3/4" water meter will be used to provide for the project's irrigation demands.

A new 8" fire line will be extended from the public main extension to serve the fire sprinkler system for the project. An 8" gate valve will be the demarcation point between the public and private water lines. The existing fire hydrant located within the right of way adjacent to the lot is within 140 feet of the proposed fire department connection located on the north face of the building. This hydrant provides adequate fire coverage for the project. Additional public hydrants are located 325 feet north and 125 feet south of the Ty Jenkins lot. No additional fire hydrants are required for this project.

See the Appendix for the proposed water layout.

A simple water model was prepared to confirm the fire demand for the building could be met with an 8" fire line. The domestic demand was ignored given the fact that if the building was burning, there would be no domestic demand. Given the proposed fire line layout, the system can provide 2,178 gpm while retaining 20 psi in the public system.

#### **EXISTING SEWER FACILITIES**

An existing 8" sewer line is located within 81st Street. This line conveys wastewater to the south and is approximately nine feet deep in the area. Based on the city's quarter section map, the 8" line has a slope of 0.0150 feet per foot. Using Manning's formula, the sewer has a capacity of 506 gpm when flowing 75% full.

#### PROPOSED SEWER FACILITIES

The minimum sewer service size for commercial land uses is 6". The Ty Jenkins Hangar will be provided with a new 6" SDR 35 PVC sewer service constructed in accordance with MAG Standard Detail 440-3. Based upon the topographic survey done for this project, the invert of the existing 8" sewer main at the proposed location of the sewer service is 1498.30. The invert of the sewer service at the sewer main will be 1498.97. The sewer service will be constructed at a slope of 1/4" per foot which equals 2.083%. The invert of the sewer service where it crosses the existing water main in 81st Street will be 1499.46. The invert of the existing 12" water main is approximately 1502.64. The new sewer service will cross under the existing water main with approximately 2.62 feet of clearance.

The 6" sewer line can convey 331 gpm when flowing 75% full. Given the peak sewer discharge from the project is 8.54 gpm, the 6" service line is more than adequate to serve this project. The depth of flow in the sewer service line was calculated at 0.6" given the peak discharge from the building. The anticipated velocity was 1.7 feet per second.

The hangar area will install a trench drain to collect water used in washing the hangar floor. This trench drain will discharge into a sand/oil separator prior to discharging to the sewer service line. The separator will be designed by the plumbing engineer. The sizing calculation provided by the plumbing engineer is included in the Appendix.

See the Appendix for the proposed sewer layout.

Copies of all calculations are also included in the Appendix.

#### Notes:

- (1) These values shall not be used directly for service line or water meter sizing.
- (2) Gallon per day values are provided for reference only. The instantaneous gallon per minute flow rates presented are intended for use in the required hydraulic modeling scenarios. The gpm values assume a 12-hour active water use period per 24-hour day. In large or specialty developments or master plans the hydraulic analysis criteria and parameters should be discussed with the Water Resources Department. Seasonal peaking should also be considered. Upon review, the Water Resources Department reserves the right to designate flows to be used in hydraulic modeling scenarios that may be different from those presented here.
- (3) The hydraulic modeling peaking factors used in select modeling scenarios are to be applied to the gpm values shown here. Max day and peak hour peaking factors can be found in Section 6-1.404.

#### HYDRAULIC DESIGN

No public SS lines will be less than 8 inches in diameter unless permission is received in writing from the Water Resources Department.

SS lines shall be designed and constructed to give mean full flow velocities equal to or greater than 2.5 fps, based upon Manning's Formula, using an "n" value of 0.013.

To prevent abrasion and erosion of the pipe material, the maximum velocity will be limited to 10 fps at estimated peak flow. Where velocities exceed this maximum figure, submit a hydraulic analysis along with construction recommendations to the Water Resources Department for consideration. In no case will velocities greater than 15 fps be allowed.

Actual velocities shall be analyzed for minimum, average day and peak day design flow conditions for each reach of pipe.

The SS system shall be designed to achieve uniform flow velocities through consistent slopes. Abrupt changes in slope shall be evaluated for hydraulic jump.

The depth to diameter ratio (d/D) for gravity SS pipes 12 inches in diameter and less shall not exceed 0.65 in the ultimate peak flow condition. This d/D ratio includes an allowance for system infiltration and inflow.

The d/D for gravity drains greater than 12 inches diameter shall not exceed 0.70 for the ultimate peak flow condition. This d/D includes an allowance for system infiltration and inflow.

Measures to mitigate hydrogen sulfide shall be analyzed at manhole drops, abrupt changes in pipe slope or direction and at changes in pipe diameter.

#### MANHOLES AND CLEAN OUTS

Manholes in city streets shall be located near the center of the inside traffic lane, rather than on or near the line separating traffic lanes. Manholes shall not be in bike trails, equestrian trails, sidewalks, crosswalks or wash crossings. Manholes are required at all
